

# C57BL/6 (Rosa-rtTA shTet3)

These reversible RNAi transgenic mice can be used to model knockdown and restoration of endogeous Tet3 in hematopoietic cells for TET3 mutant diseases.

These are Doxycycline-inducible transgenic mice expressing shRNAs that target the Tet3 gene. To model reversible Tet3 knockdown, researchers created transgenic mice that express a Tet3-specific shRNA regulated by doxycycline (Dox) from the Col1a1 locus. These mice were bred with two types of transactivator mice: Vav-tTA (VTA) mice, which have a pan-hematopoietic, Dox-off tTA transactivator, and ROSA26-M2rtTA (RTA) mice, which have a ubiquitously expressed, Doxon M2rtTA transactivator. The resulting progeny exhibit Dox-regulated Tet3 gene knockdown or restoration.
